# Our Team

**Jonathan Lin**  
Project Leader

**Andrew Chen**

**Dhanya Jayagopal**

**Joey Nguyen**

**Kevin Lin**

**Chelsea Chen**

# Goals of Project

## Cohesion

- Want result to sound like music
- Not too “random”

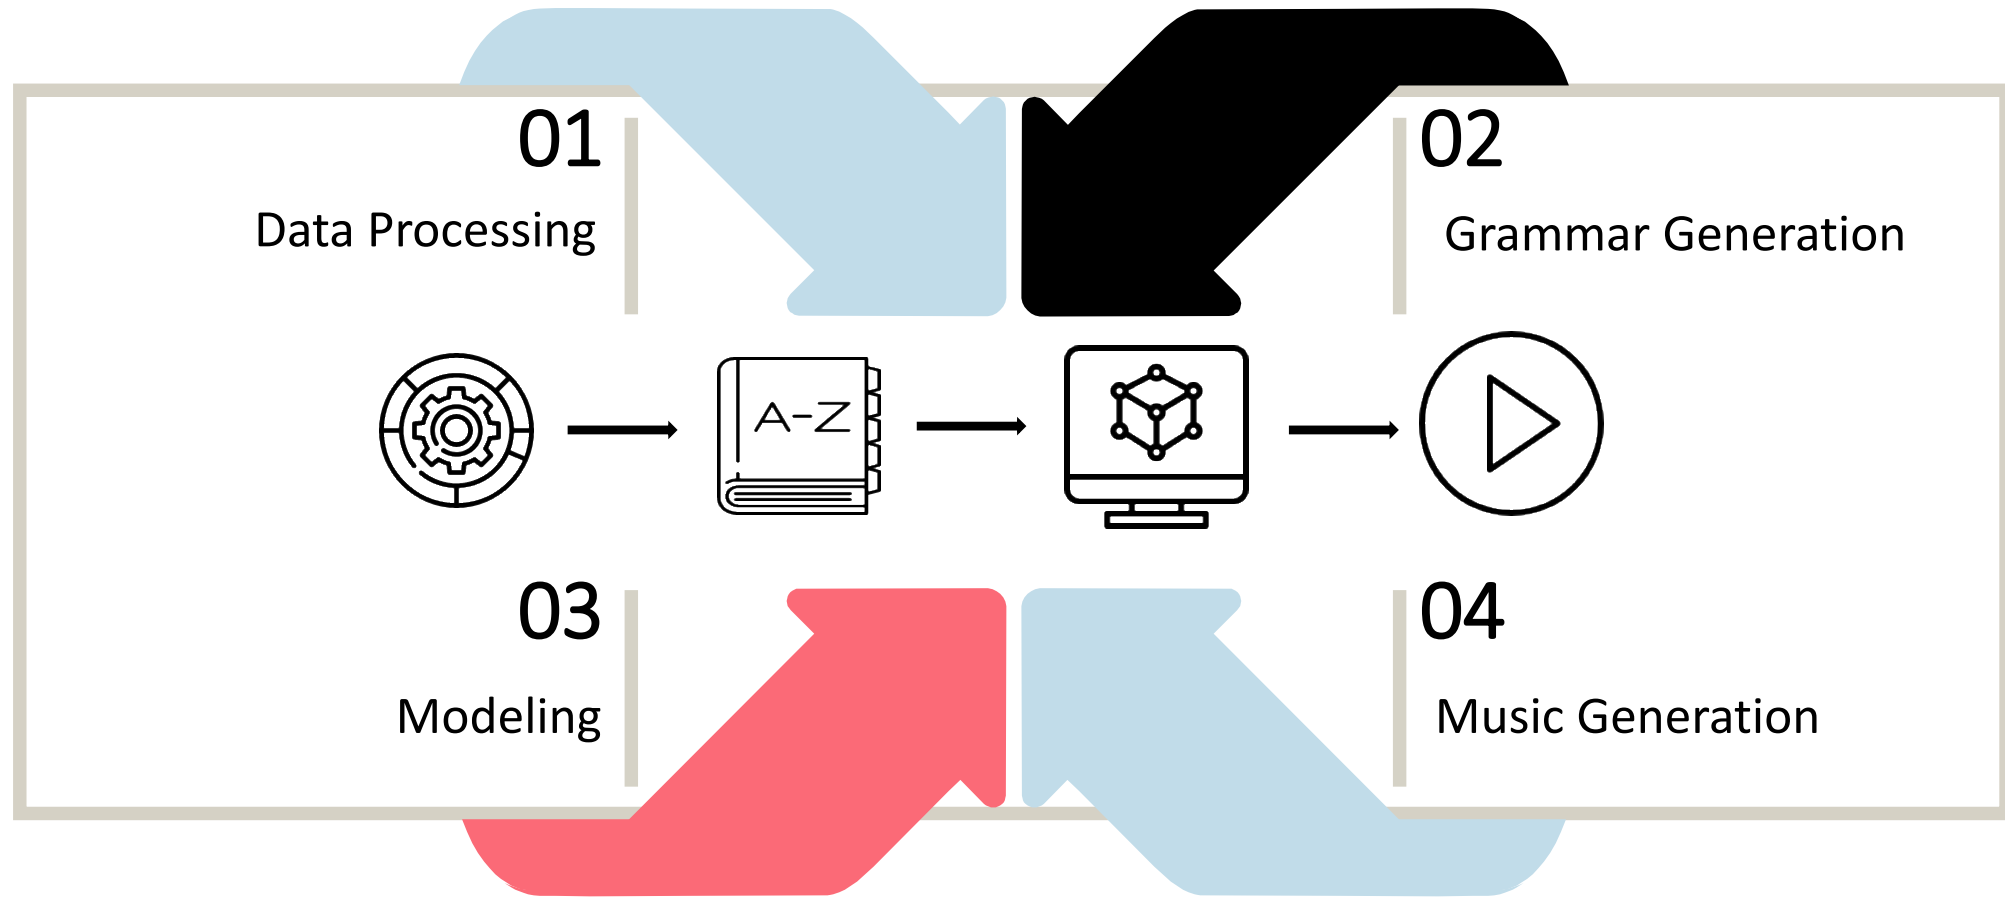

## Originality

- Does not too closely imitate training data

## Emulation

- Sounds like the style of original artist

# Project Overview

# Data Processing

# Data Processing

Finding **MIDI** files of  
jazz solos

Extract relevant  
information and store  
into CSV files

Find **note name, start  
time, duration, and chord**

# Grammar Generation

# Generating *S-Expressions*

## *S-Expressions*

**Backbone** of our method of  
grammar generation  
Encapsulates the **style of the piece**

- Represents **one measure**
- Contains **max/min “slope”** of the measure
- For each note in measure:
  - Categorize based on **chord type**
  - Categorize based on number of **half steps away from root**

# Featurization

For each *s-expression*, we calculated **6 features**:

number of notes

average maximum slope

location of first note

order of the contour

total duration of rests

consonance

We **normalized** these features to prepare for the next part of the project.

# Modeling

# Clustering and Probabilistic Chaining

1. Run **K-Means** using the six features from before to create clusters of *s-expressions*

2. Generate a **Markov Model**: CPTs that reveals which cluster of are likely to follow another, attempting to model the musician's style of playing

# Note Resolution, Interval Generation

## Note Resolution

- Hop through the Markov Model
- Probabilistically choose *s-expressions* within successive nodes
- Select notes within chosen *s-expressions*

## Interval Generation

- Probabilistically add intervals to generate chords
- Add intermittent notes to simulate improvisation
